

Simulation of Surface Plasmon Resonance in Nanoparticle Array Using EM Explorer

8/19/07

www.emexplorer.net

Overview

- The interaction of planewaves with an array of nano-particles was simulated using EM Explorer, an FDTD-based 3D EM solver.
- The surface plasmon resonance was found at wavelength ~367nm for a square array of silver spheres (50nm diameter, 300nm center-to-center distance) in air.
- The EM field around the particle at the resonance wavelength was examined in detail in this work and was compared with that of a wavelength far off the resonance.

Optical Properties of Bulk Silver

- The following n & k properties of the bulk silver material (P.B. Johnson and R.W. Christy, Phys. Rev. B. 6(12) 4370-4379, 1972) was used in the simulation.

- The data indicates that the resonance wavelength of a single Ag particle in air is $\sim 354\text{nm}$ (Metal nanoparticle arrays for near field optical lithography, Pieter G. Kik, Andrea L. Martin, Stefan A. Maier, and Harry A. Atwater, Proceedings of SPIE 4810 (2002))

EM Explorer Simulation Conditions

- 2D square array of Ag spheres:

- Diameter: 50nm
- Center-to-center distance: 300nm
- Periodic boundary in x and y
 - Only one unit needs to be simulated
- Ambient: air

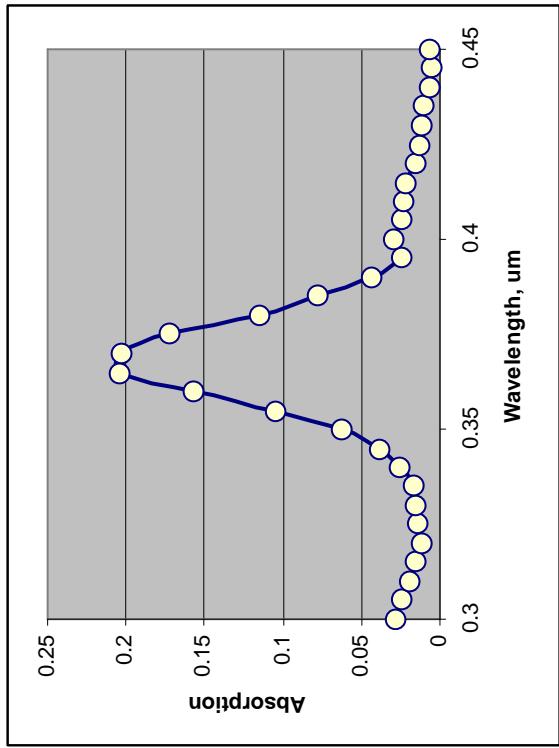

- Planewave illumination:

- Normal incidence (+z)
- Polarization in x direction
- Wavelength: 300nm to 450nm

- Post-processing: Absorption $A = (I - T - R) / I$

- I = incident energy, T = transmitted energy, R = reflected energy

Simulated Absorption Spectrum

□ The data indicates resonance wavelength of ~367nm
